AML Classification - ICC

ICC AML

AML with recurrent genetic abnormalities (requiring ≥10% blasts in BM or PB)^a
• APL with t(15;17)(q24.1;q21.2)/PML::RARA^b • AML with t(8;21)(q22;q22.1)/RUNX1::RUNX1T1 • AML with inv(16)(p13.1q22) or t(16;16)(p13.1;q22)/CBFB::MYH11 • AML with t(9;11)(p21.3;q23.3)/MLLT3::KMT2A^b • AML with t(6;9)(p22.3;q34.1)/DEK::NUP214 • AML with inv(3)(q21.3q26.2) or t(3;3)(q21.3;q26.2)/GATA2, MECOM(EVI1)^b • AML with other rare recurring translocations • AML with mutated NPM1 • AML with in-frame bZIP mutated CEBPA^c • AML with t(9;22)(q34.1;q11.2)/BCR::ABL1^a
Categories designated AML (if ≥20% blasts in BM or PB) or MDS/AML (if 10-19% blasts in BM or PB)
• AML with mutated TP53^d • AML with myelodysplasia-related gene mutations Defined by mutations in ASXL1, BCOR, EZH2, RUNX1, SF3B1, SRSF2, STAG2, U2AF1, or ZRSR2 • AML with myelodysplasia-related cytogenetic abnormalities^e • AML not otherwise specified (NOS)

^a Bone marrow or peripheral blood blast count of ≥10% required, except for AML with t(9;22)(q34.1;q11.2); BCR::ABL1.

^b Variant rearrangements involving RARA, KMT2A, or MECOM should be recorded accordingly.

^c AML with in-frame mutation in the bZIP domain of the CEBPA gene, either monoallelic or biallelic.

^d The presence of a pathogenic somatic TP53 mutation (at a variant allele fraction of at least 10%, with or without loss of the wild-type TP53 allele) defines the entity AML with mutated TP53.

^e Cytogenetic abnormalities sufficient for the diagnosis of AML with MDS-related cytogenetic abnormalities and the absence of other AML-defining disease categories.

o Complex karyotype: ≥3 unrelated chromosome abnormalities in the absence of other class-defining recurring genetic abnormalities.

o Unbalanced clonal abnormalities: del(5q)/t(5q)/add(5q); -7/del(7q); +8; del(12p)/t(12p)/(add(12p); i(17q), -17/add(17p) or del(17p); del(20q); and/or idic(X)(q13)

Major changes

- Changes concerning **blast thresholds** defining AML
 - **≥10% blasts** → AML with recurrent genetic abnormalities
 - **10-19% blasts** → other categories → MDS/AML (genetic and clinical continuum)
 - **≥20% blasts** → AML
- Introduction of new **genetically defined entities**
 - AML with mutated TP53
 - AML with myelodysplasia-related gene mutations (high association with sAML after prior hematologic neoplasms)
 - AML with myelodysplasia-related cytogenetic abnormalities
- **Pre-existing AML** in medical history
 - MDS or MDS/MPN no separate categories but rather classified as „qualifiers“

AML Risk Classification - ELN

ELN risk classification 2022

Risk Category	Genetic Abnormality
Favorable	- t(8;21)(q22;q22.1)/<i>RUNX1::RUNX1T1</i> - inv(16)(p13.1q22) or t(16;16)(p13.1;q22)/<i>CBFB::MYH11</i> - Mutated <i>NPM1</i>^a without <i>FLT3-ITD</i> - bZIP in-frame mutated <i>CEBPA</i>
Intermediate	- Mutated <i>NPM1</i>^a with <i>FLT3-ITD</i> - Wild-type <i>NPM1</i> with <i>FLT3-ITD</i> - t(9;11)(p21.3;q23.3)/<i>MLLT3::KMT2A</i> - Cytogenetic and/or molecular abnormalities not classified as favorable or adverse
Adverse	- t(6;9)(p23;q34.1)/<i>DEK::NUP214</i> - t(v;11q23.3)/<i>KMT2A</i>-rearranged - t(9;22)(q34.1;q11.2)/<i>BCR::ABL1</i> - t(8;16)(p11;p13)/<i>KAT6A::CREBBP</i> - inv(3)(q21.3q26.2) or t(3;3)(q21.3;q26.2)/<i>GATA2,MECOM(EVI1)</i> - t(3q26.2;v)/<i>MECOM(EVI1)</i>-rearranged -5 or del(5q); -7; -17/abn(17p) - Complex karyotype, monosomal karyotype - Mutated <i>ASXL1, BCOR, EZH2, RUNX1, SF3B1, SRSF2, STAG2, U2AF1, or ZRSR2</i> - Mutated <i>TP53</i>

Major changes

- **AML with FLT3-ITD now categorized as intermediate risk**
 - irrespective of allelic ratio and NPM1 status
 - Impact of midostaurin-based therapy
- **Prognostic impact of myelodysplasia-related gene mutations or s-AML → adverse**
 - *ASXL1, BCOR, EZH2, RUNX1, SF3B1, SRSF2, STAG2, U2AF1, ZRSR2*
- **Prognostic impact of CEBPA mutation, now → favorable**
 - *CEBPA*^{bZIP-inf} shows significantly superior outcome

WHO 5th edition

AML with defining genetic abnormalities (no blast threshold)*

Fusion:

- RUNX::RUNX1T1
- CBFB::MYH11
- DEK::NUP214
- RBM15::MRTFA
- BCR::ABL1*

Rearrangement (may be cryptic):

- KMT2A
- MECOM
- NUP98

AML-MR* defined by:

- **Molecular abnormality**
- Cytogenetic abnormality
- **Prior History of MDS or MDS/MPN**

Molecular:

- NPM1 mutation
- CEBPA mutation*

AML with other defined genetic alterations

No

AML defined by differentiation (Blasts $\geq 20\%$)

- AML with minimal differentiation
- AML Without maturation
- AML with maturation
- Acute basophilic leukemia
- Acute myelomonocytic leukemia
- Acute monocytic leukemia
- Acute erythroid leukemia
- Acute megakaryoblastic leukemia

Separate group of secondary myeloid neoplasms

Post cytotoxic therapy
Associated with
germline predisposition

ICC

AML with recurrent genetic abnormalities (10% blast threshold)

- RUNX::RUNX1T1
- CBFB::MYH1
- DEK::NUP214
- KMT2A rearrangement
- MECOM rearrangement
- Other rare recurring translocations
- BCR::ABL*
- NPM1 mutation
- In-frame bZIP CEBPA mutation

No

AML with mutated TP53 (VAF $>10\%$)

No

AML with myelodysplasia- related gene mutation

No

AML with myelodysplasia- related cytogenetic abnormality

No

AML – NOS

MRD

Approaches for the detection of MRD in patients with AL.

Technique	MFC	RQ-PCR and ddPCR	NGS	sDNAseq
Target	Aberrant immunophenotype	Ig/TCR; fusion genes; gene mutation	Ig/TCR; gene mutation	Gene mutation
Specimen	Fresh viable cells obtained from PB, BM, or tissues	DNA or RNA	DNA	DNA
Applicability	AML: >90% ALL: >95%	AML: Fusion genes and mutation: 40%–50% ALL: Ig/TCR >90%; fusion genes: 35%–45%	AML: nearly for all patients ALL: >90%	AML: nearly for all patients
Sensitivity	AML: 10 ^{−4} (LAIP and DfN based); 10 ^{−5} (LSC-based) ALL: 10 ^{−5}	AML: 10 ^{−4} –10 ^{−5} ALL: 10 ^{−4} –10 ^{−5}	AML: 10 ^{−2} –10 ^{−6} ALL: 10 ^{−6}	AML: 10 ^{−2} –10 ^{−3} ALL: NA
Routine use	Yes	Yes	No (clinical trial)	No (in research)
Standardization	Limited	Good, such as Ig/TCR and BCR/ABL	Good	No
Advantages	• High sensitivity (for NGF) • No access to diagnostic sample • Relatively inexpensive	• High sensitivity and specificity • Patient-specific methods • Easy-to-use	• Very high sensitivity • Potential to track small subclones and clone evolution • Relatively fast	Broad applicability Accurately resolve clonal architectures and identify clonal origins of drug resistance Determine specific alterations in immunophenotype depending on clonality
Disadvantages	• Requires no individual optimization • Fast (within 24 h) • Fresh samples are needed • Confounders, such as phenotype shift and hematogone during marrow recovery • Skilled experts are required	• Broad applicability • Expensive • Might miss small subclones or clonal evolution • Time-consuming • Skilled experts are required • Slow • Need diagnostic sample	• Broad applicability • Expensive • Highly specialized bioinformatics approaches and expertise are needed • Need diagnostic sample • Few experienced laboratory • Confounders, such as CHIP	Expensive and low throughout Highly specialized bioinformatics approaches and experts are needed Low sensitivity and need diagnostic sample Few experienced laboratory Small mutation panels and allelic dropout

Table 1. MDS entities according to WHO-HAEM5 2022 and ICC 2022 classifications

WHO-HAEM5 2022	ICC 2022
MDS with defining genetic abnormalities MDS with low blasts and isolated 5q deletion MDS with low blasts and <i>SF3B1</i> mutation* MDS with biallelic <i>TP53</i> inactivation	MDS with del(5q) MDS with mutated <i>SF3B1</i> MDS with mutated <i>TP53</i>
MDS, morphologically defined MDS with low blasts (<5% blasts; dysplasia is a prerequisite) MDS with low blasts and single-lineage dysplasia (MDS-LB-SLD) MDS with low blasts and multilineage dysplasia (MDS-LB-MLD) MDS with ring sideroblasts (MDS-RS) MDS, hypoplastic (<5% blasts) MDS with increased blasts (5% to <20% blasts) MDS-IB1 (5% to <10% blasts) MDS-IB2 (10% to <20% blasts) MDS with fibrosis (5% to <20% blasts)	MDS, NOS without dysplasia MDS, NOS with single lineage MDS, NOS with multilineage dysplasia MDS with excess blasts (5% to <10% blasts) MDS/AML (10% to <20% blasts)

Table 2. MDS entities defined by genetic abnormalities in the ICC and WHO-HAEM5

WHO-HAEM5	ICC	Implications of genomic profiling
MDS with low blasts and isolated 5q deletion BM blasts of <5% del(5q) alone or with 1 additional abnormality, except -7/del(7q) Any somatic mutation, except biallelic <i>TP53</i> inactivation	MDS with del(5q) BM blasts of <5% del(5q) alone or with 1 additional abnormality, except -7/del(7q) Any somatic mutation, except biallelic <i>TP53</i>	Genomic profiling is fundamental to diagnosis. Patients with biallelic inactivation of <i>TP53</i> have poor outcomes and are therefore classified as <i>TP53</i> -mutant MDS.
MDS with low blasts and <i>SF3B1</i> mutation BM blasts of <5% Absence of del(5q), -7, or complex karyotype <i>SF3B1</i> mutation, no biallelic <i>TP53</i>	MDS with mutated <i>SF3B1</i> BM blasts of <5% Absence of del(5q), -7/del(7q), abn3q26.2, or complex karyotype <i>SF3B1</i> mutation (VAF ≥10%), no biallelic <i>TP53</i> inactivation, no <i>RUNX1</i> mutation	Genomic profiling is fundamental to diagnosis (exclusion of biallelic inactivation of <i>TP53</i>) and important for prognosis. Patients with comutation patterns in other genes such as <i>BCOR</i> , <i>BCORL1</i> , <i>NRAS</i> , <i>RUNX1</i> , or <i>STAG2</i> have worse clinical outcomes.
MDS with biallelic <i>TP53</i> inactivation BM blasts of <20% Two or more <i>TP53</i> mutations, or one mutation with evidence of <i>TP53</i> copy number loss or cnLOH Usually complex karyotype	MDS with mutated <i>TP53</i> BM blasts of 0%-9% Biallelic <i>TP53</i> inactivation* or <i>TP53</i> mutation (VAF >10%) and complex karyotype often with loss of 17p† MDS/AML with mutated <i>TP53</i> BM blasts of 10%-19% Any somatic <i>TP53</i> mutation (VAF >10%)	This condition is associated with exceptionally poor clinical outcomes. The identification of a biallelic <i>TP53</i> inactivation requires the implementation of ad hoc copy number and LOH analysis.

Table 3 IPSS-M risk score, risk categories, and clinical outcomes

Risk category	IPSS-M score	Median leukemia-free survival (y)	Median OS (y)	AML transformation by 1 y (%)
Six-category risk schema				
Very low (14% of all patients)	Less than or equal to −1.5	9.7	10.6	0
Low (33%)	More than −1.5 to −0.5	5.9	6.0	1.7
Moderate low (11%)	More than −0.5 to 0	4.5	4.6	4.9
Moderate high (11%)	>0 to 0.5	2.3	2.8	9.5
High (14%)	>0.5 to 1.5	1.5	1.7	14.3
Very high (17%)	>1.5	0.7	1.0	28.2
Lower-risk vs higher-risk MDS				
Lower-risk MDS (58%)	≤0 (negative value)	6.0 (95% CI, 5.7-6.7)	6.3 (95% CI, 5.8-7.2)	2.0
Higher-risk MDS (42%)	>0 (positive value)	1.2 (95% CI, 1.1-1.3)	1.5 (95% CI, 1.4-1.6)	18.9

Table 4. Genetically derived subgroups of MDS that have been defined in the ad hoc study of the International Working Group for Prognosis in MDS

Molecular subgroup	Clinical features, outcomes, and disease-related eligibility for allogeneic transplantation
Morphological MDS with the absence of recurrent genetic events in myeloid genes	Good OS with low risk of leukemic transformation. Most patients are not transplant candidates. Patients with VEXAS and severe rheumatic disease may be considered.
<i>SF3B1</i> -mutant MDS	Indolent clinical course with low risk of leukemic transformation. Most of these patients are not transplant candidates.
<i>ZRSR2</i> -mutant MDS	Male patients with refractory macrocytic anemia, no excess blasts, and indolent clinical course. These patients are not transplant candidates.
MDS NOS	Mild phenotype and favorable outcomes in most patients. Most of these patients are not transplant candidates.
CCUS-like MDS	Mild phenotype and favorable outcomes in most patients. Most of these patients are not transplant candidates.
MDS del(5q)	Well-established MDS subtype whose outcomes are determined by comutation patterns. Patients with comutation in <i>SF3B1</i> , <i>RUNX1</i> , or <i>TP53</i> should be considered for allogeneic transplantation.
MDS with biallelic <i>TET2</i> mutation	Older patients, monocytosis overlapping with CMML. Indolent clinical course in most patients. Most of these patients are not transplant candidates.
<i>DDX41</i> -mutant MDS	Cytopenia with hypoplastic bone marrow with excess blasts. Disorder with high risk of leukemic evolution, but favorable prognosis compared with other MDS with excess blasts. Genomic diagnosis is crucial in the transplantation setting for donor selection and prevention of acute GVHD with PTCy. All patients are potential transplant candidates.
<i>U2AF1</i> -mutant MDS <i>SRSF2</i> -mutant MDS <i>BCOR/L1</i> -mutant MDS <i>IDH-STAG2</i> -mutant MDS MDS with der(1;7) -7/ <i>SETBP1</i> -mutant MDS <i>EZH2-ASXL1</i> -mutant MDS	Aggressive diseases with poor survival and high risk of leukemic transformation. Although specific agents targeting the driver mutation are being developed (such as spliceosome inhibitors, ivosidenib, or enasidenib). These patients are potential transplant candidates.
AML-like MDS	Biologically this condition resembles AML, except for <20% bone marrow blasts. All patients are potential transplant candidates.
<i>TP53</i> -complex MDS	Extremely aggressive disease with a median survival <1 year. Poorly responsive to any currently available treatment. High relapse rate after transplantation. All patients are potential transplant candidates, preferably within a clinical trial.

Key recommendations

- The patient's eligibility for allogeneic transplantation should be assessed at the time of diagnosis of MDS.
- Disease- and patient-related risk factors, as well as donor availability, and the patient's values and wishes, should be considered when assessing eligibility for transplantation.
- Evaluation of the MDS risk, requires the calculation of the IPSS-M score, based on conventional cytogenetics, genomic profiling, and *TP53* allelic state. Additionally, germ line testing is needed for identifying genetic predisposition to MDS.
- All patients with higher-risk MDS (according to IPSS-M) are potential candidates for immediate transplantation. A subset of patients with lower risk MDS may also benefit from this procedure at an earlier stage of the disease.
- Assessment of patient-related risk factors should consider performance status, comorbidities, and frailty.
- Although accurate assessment of biological age has made allogeneic transplantation a feasible option for patients with MDS up to the eighth decade of life, this procedure should generally be avoided in patients aged >80 years.
- HLA-matched relatives, MUDs, and haploidentical donors can be used for patients with MDS undergoing allogeneic transplantation, with a preference for younger donors in the selection algorithm.
- The choice of intensity of the conditioning regimen must consider not only chronological age but also a comprehensive assessment of organ/system function and disease characteristics.
- Patients with MDS with blast excess ($\geq 10\%$) may benefit from cytoreductive therapy before allogeneic transplantation, but results of ongoing clinical trials are needed for more definitive conclusions.
- Measurable residual disease assessment is recommended after allo-HCT regardless of MDS risk, but there is insufficient evidence to recommend prophylaxis or maintenance.
- Posttransplant therapeutic strategies for patients with measurable residual disease or relapsed patients include treatment with HMAs and DLI.

Baldus, MD¹¹; Jolana Mertová, MD¹²; Edgar Jost, MD¹³; Dirk Niemann, MD¹⁴; Jan Novák, MD¹⁵; Stefan W. Krause, MD¹⁶ ; Sebastian Scholl, MD¹⁷; Andreas Hochhaus, MD¹⁷ ; Gerhard Held, MD¹⁸; Tomas Szotkowski, MD¹⁹ ; Andreas Rank, MD²⁰; Christoph Schmid, MD²⁰ ; Lars Fransecky, MD¹¹ ; Sabine Kayser, MD^{21,22,23}; Markus Schaich, MD²⁴; Michael Kramer, MSc¹; Frank Fiebig, MSc¹; Annett Haake, BSN¹; Johannes Schetelig, MD¹ ; Jan Moritz Middeke, MD¹ ; Friedrich Stölzel, MD¹¹; Uwe Platzbecker, MD²¹ ; Christian Thiede, MD^{1,25} ; Carsten Müller-Tidow, MD⁹ ; Wolfgang E. Berdel, MD³ ; Gerhard Ehninger, MD¹; Jiri Mayer, MD⁷ ; Hubert Serve, MD² ; and Martin Bornhäuser, MD¹ 

FIG 1. CONSORT diagram on random assignment and treatment. CR, complete remission; ITT, intent-to-treat principle in the full analysis set; PP, per-protocol analysis set.

AML Summary fit

- Induction fit
- 7 +3 (5+2 ?)
- Study when possible
- FLT3+: + Midostaurin
- t-AML, AML-MRC: CPX-351
- CD33+: Gemtuzumab Ozogamicin bei CBF oder NPM1mut/FLT3wt
- Consolidation:
- Good: 3 Zyklus Chemo (Mitoxantron/Etoposide. HD-Cytarabine bei CBF-AML)
- Bad: allo-HSCT
- Intermediate: allo-HSCT. donor availability ? MRD ?
- Maintenance
- CC-486 in CR (CAVE Zulassung)
- Post-allo: Sorafenib bei FLT3+
- Azacitidine/Venetoclax (prä-HSCT Persistenz). Decitabine (bei TP53) (CAVE Zulassung)
- ± DLI

AML Summary unfit

- Azacitidine/Venetoclax
- IDH1 Inhibitor/Azacitidine
- FLT3+: Midostaurin
- IDH2 Inhibitor (Cave Zulassung)
- LDAC
- LDAC + Glasdegib
- CC-486 in CR

Thank you for your
attention
